New Myobiidae (Acarina: Trombidiformes) from Philippine Mammals

KIMITO UCHIKAWA¹, BARRY M. OCONNOR² and HANS KLOMPEN²

¹Department of Parasitology, Shinshu University School of Medicine, Matsumoto 390, Japan, and ²Museum of Zoology and Department of Biology, The University of Michigan, Ann Arbor, Michigan 48109, U.S.A.

ABSTRACT—Four new species of myobiid mites are described from mammals from the Philippines: Ugandobia saccolaimis sp. n., from Saccolaimus saccolaimus (Emballonuridae); Metabinuncus obscuris sp. n., from Hipposideros obscurus (Hipposideridae); Pteracarus kervoulis sp. n., from Kerivoula hardwickii (Vespertilionidae); and Myobia apomyos sp. n., from Apomys littoralis (Muridae). One new subspecies, Ugandobia balionycteris leyteensis ssp. n., from Emballonura alecto (Emballonuridae), is also described. Apparent sexual dimorphism and precocious development of female genital structures were observed in the immature stages of the two Ugandobia mites.

INTRODUCTION

As part of continuing studies on the systematics and ecology of Philippine mammals initiated by Dr. L. R. Heaney, now of the Field Museum of Natural History in Chicago, USA, we have had the opportunity to examine extensive collections of fresh and fluid preserved mammal specimens in order to remove parasitic arthropods. In this paper, we report on a collection of Myobiidae (Acari) taken from bats and rodents from the islands of Negros, Leyte and Maripipi in the central Philippines. Because some of the hosts belong to groups either undergoing revision or awaiting revision, host identifications are in some cases tentative. Accurate identification of host species is absolutely essential for studies on coevolution of hosts and parasites [1, 2]. In order that future workers will be able to verify the identity of host species cited here by reexamining the actual host specimens, we provide full voucher data for each host, including museum catalogue numbers (where available), collector's field numbers and parasite voucher numbers.

MATERIALS AND METHODS

All hosts were collected during the first half of 1987 as part of the Visayan Mammal Survey. Bats were caught in mist nets set on ridgetops and across trails (Hipposideros, Kerivoula), or in their roosts in trees (Saccolaimus) and caves (Emballonura). Rodents such as Apomys were collected in various types of rat traps [3]. Freshly killed hosts were examined in the field by one of us (H.K.) and mites were collected using standard watchmaker's forceps and a 20X dissecting microscope. Collections from each host individual were stored in vials with 70% ethanol until return to the U.S.A. In the laboratory, mites were mounted on sides in Berlese's medium, identified to genus, and were sent to the senior author. We all have deliberated and agreed upon the identifications below.

Mite specimens are deposited in the University of Michigan Museum of Zoology, Ann Arbor, Michigan, USA (UMMZ), the U.S. National Museum of Natural History, Washington, D.C., USA (NMNH), the Philippine national acarological collection, presently housed at Visayas State College of Agriculture, Baybay, Leyte, the Philippines (VISCA), and in the collection of the senior author (KU). Host specimens were preserved as fluid preparations (F) or skeleton preparations (S)

and are deposited in the NMNH and the Western Australian Museum, Perth, Australia (WAM).

In the following descriptons, all measurements are given in micrometers (μ m).

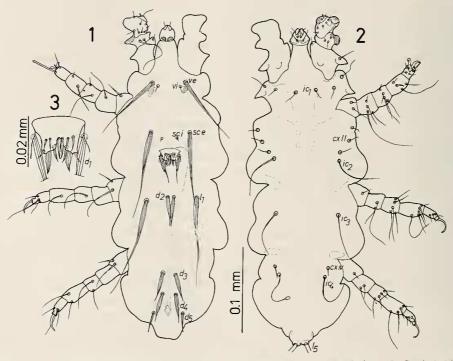

DESCRIPTIONS

Ugandobia saccolaimis sp. n. (Figs. 1-6)

Male (Figs. 1–3). Measurements for holotype and, in parentheses, for 2 paratypes are given. Body (gnathosoma and idiosoma) 370 (370–360) long by 140 (143–135) wide; idiosoma elongate. Dorsal seta vi setiform, 10 (10–10) long; ve 5 (5–5) wide and 85 (80–>75) long; sc i setiform, 5 (5–5) long, situated slightly posterior to basal level of sc e; sc e 6 (6–7) wide and 110 (>95–98) long; l_1 6 (7–6) wide, about 120 (118-105) long; d_1 with base imbedded in cuticle close to genital shield, denticulate and striated, 32 (30–28) long; d_2 swollen in proximal one third, emerging slightly from basal level of l_1 , 45 (53–45) long; d_{3-4} swollen, 32 (33–

32) and 35 (38–33) long, respectively; d_5 tapering, 22 (18–17) long. Genital shield situated posteriad from sc e, bearing 6 pairs of genital setae (Fig. 3). Penis thin, about 190 (ca. 200-ca. 190) long. Ventral setae $ic_1>23$ (>25–33) long; ic_{2-4} much longer than ic_1 ; coxal setae 2-3-0-1; basal circle of each ventral seta clear. Leg l as in Figures 1 and 2. Chaetotaxy on legs II-IV: trochanters 3-3-3; femora 5-2-2; genua 7-6-6; tibiae and tarsi 6-6-6. Gnathosoma small, and almost circular dorsally; ventral sclerites not so prominent.

Female (Fig. 4). Measurements for allotype and, in parentheses, for 3 paraytpes are given. Body 500 (490–510) long by 185 (180–190) wide; idiosoma elongate. Dorsal seta vi setiform, 13 (12-13) long; ve 5 (6–7) wide and >75 (77–83) long; sc i 6 (7–8) wide, 60 (55–58) long; sc e as wide as sc i, 108 (100–108) long; l_1 8 (8–8) wide, 98 (80–90) long; d_{1-2} and l_2 swollen, maximum width about 10, 53 (52–55), 47 (47–52) and 45 (45–45) long, respectively; d_1 distinctly emerging from bases of l_1 ; d_{3-4} swollen, but thinner than preceding setae, 48 (45–45) and 45 (44–45) long, respec-

Figs. 1-3. Ugandobia saccolaimis sp. n., male. 1: Dorsal view. 2: Ventral view. 3: Genital shield.

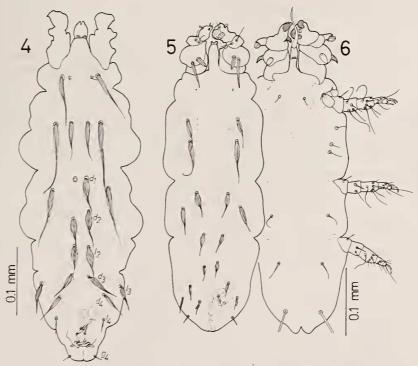

tively; l_3 swollen, weakly denticulate, 38 (40–43) long; l_4 thin, 36 (27–35) long. Genital seta g_7 blade-like, on well-developed lobe-like structure; g_5 thick; g_6 minute. Spermatheca bell-shaped, 20 (22–23)×12 (12–15). Ventral setae as in male; g_1 and g_3 present. Legs and gnathosoma as in male.

Tritonymph (Figs. 5-6). Body 432-360 long and 153-140 wide; idiosoma elongate. Dorsal setation as in Figure 5; only 2 pairs of propodosomal setae (ve, sc e) and, as in female, 8 pairs of hysterosomal setae present; l₅ on venter; hysterosomal setae other than l_4 swollen and striated. Coxal chaetotaxy 2 (circular, transparent)-2-0-0. bilaterally asymmetric; some ventral setae of segments of leg I transparent and difficult to observe. Chaetotaxy on legs II-IV: trochanters 1-1-1; femuro-genua 4-2-2; tibiae 6-5-5; tarsi 6-6-6. Anal shield discernible only on smaller individual almost at basal level of l_4 and lacking on larger individual. Spermatheca bell-shaped, 25×12, discernible only in larger individual; genital opening subterminal on midline (Fig. 5).

Protonymph. Body 223 long by 100 wide. Two pairs of propodosomal setae and 7 pairs of hysterosomal setae presnet; l_4 lacking; all setae thick and striated as in tritonymph; l_5 on venter. Coxal setation 1(circular)-0-0-0. Legs I asymmetric. Chaetotaxy on legs II-VI: trochanters 0-0-0; femuro-genua 4-1-0; tibiae 5-4-4; tarsi 6-6-6.

Larva. Body 210 long by 95 wide. A pair of propodosomal and 6 pairs of hysterosomal setae present; l_5 denticulate and ending in notched tip; only a single pair of setae, ic_1 , present ventrally. Legs I symmetric. Chaetotaxy on legs II-III: trochanters 0-0; femuro-genua 2-0; tibiae 5-4; tarsi 6-6.

Material examined: Holotype male, paratype male, paratype female, ex Saccolaimus saccolaimus pluto (Chiroptera: Emballonuridae), PHI-LIPPINES: Negos Oriental Prov., Dumaguete City, 9°18′N, 123°18′E, elev. 5 m., 1 March 1987, collector D. Kitchener (P 79), host in WAM (F), mite collection number HK 87-0301-2; allotype female from same host and locality, 27 February

Figs. 4-6. Ugandobia saccolaimis sp. n. 4: Female dorsum. 5: Tritonymphal dorsum. 6: Ventral view of Tritonymph.

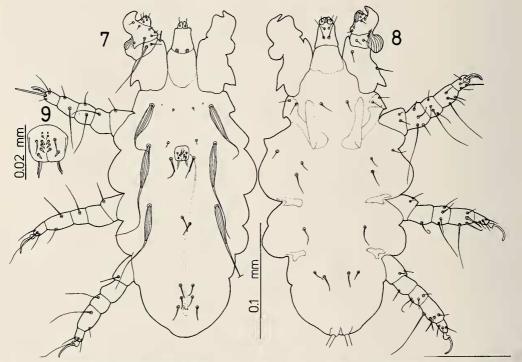

1987, collector L. R. Heaney (LRH 2956), host in NMNH (F) (catalogue number 459338), HK 87-0227-14; paratype female, protonymph, and larva from same host and locality, 27 February 1987, collector D. Kitchener (P 42), host in WAM (F), HK 87-0227-10; paratype male, paratype female, 2 paratype tritonymphs from same host and locality, 27 February 1987, collector D. Kichener (P 43), host in WAM (F), HK 87-0227-11. Mites were recovered from the chin and body venter of the hosts. Holotype, allotype and paratypes in UMMZ, other paratypes in NMNH, VISCA, KU.

Remarks. Ugandobia saccolaimis sp. n. is the 8th species of the genus Ugandobia Dusbábek, which shows the coxal chaetotaxy 2-3-0-1. The new mite is easily separable from the 4 known species described from both sexes or male, Ugandobia barnleyi (Radford), Ugandobia euthrix Fain, Ugandobia australiensis Fain and Lukoschus and Ugandobia dissimilis Uchikawa and Kobayashi, by the nature of the genital setae, position of d_2 and nature of d_{3-4} . The new species is uniquely characterized by thick and striated genital setae as in Figure 3 and the combination of d_2 slightly

emerging from bases of l_1 and swollen d_{3-4} . Among the three other species known only from the female, Ugandobia vachoni Fain and Ugandobia taphozous Fain share the minute and setiform vi with U. saccolaimis. However, the setae d_{1-2} and l_2 are not as swollen in those two species as in the new species. The immature stages except the deutonymph are also described above for U. saccolaimis. Of the previously known species, only the deutonymph, protonymph and larva of U. dissimilis have been described [4]. The protonymph and larva of both species are separable from each other by the difference in form of the setae on the idiosoma and legs, suggesting the feasibility of classifying *Ugandobia* mites in the early immature stages. In the trionymphal stage of *U. saccolaimis*, there were two morphologically different forms. One was larger than the other, lacked an anal shield and bore visible internal copulatory organs.

Ugandobia balionycteris leyteensis ssp. n. (Figs. 7–11)

Male (Figs. 7-9). Measurements for holotype

Figs. 7-9. Ugandobia balionycteris leyteensis ssp. n., male. 7: Dorsal view. 8: Ventral view. 9: Genital shield.

and one paratype are given. Body 280-270 long by 135-135 wide; hysterosoma short and narrow. Dorsal setae vi minute (about 4 long), at level of bases of ve; ve 9-10 wide and about 80-75 long; sc i slightly emerging from basal level of sc e, 6-5 long; sc e 7-8 wide, $80-93 \log; l_1 8-7$ wide, $90-85 \log;$ d_1 close to genital shield, thin and denticulate, 20-23 long; d_2 situated posterial from basal level of l_1 , thin and 12-13 long; d_{3-5} short. Genital shield situated slightly posterior to basal level of sc e, bearing 7 pairs of minute and 2 pairs of prominent setae (Fig. 9). Penis thin, about 140-130 long. Ventral setae rather short; ic1 and cx I almost on the same level; distance ic2-ic2 greater than or equal to cx II₁-cx II₁; coxal setae 2-2-0-1. Leg I as in Figures 7 and 8. Chaetotaxy on legs II-IV: trochanters 3-3-3; femora 5-1-1; genua 6-6-5 (dorsal seta lacking); tibiae 6-6-6; tarsi 7-6-6. Gnathosoma distinctly longer than wide (Figs. 7 and 8), with concave lateral margins.

Female. Dorsal setae ve thick; sc i relatively long and slightly more slender than sc e; d_1 and l_1 on the same level; d_1 , d_2 and l_3 similar in form to each other, but decreasing in thickness in this order; d_3 , d_4 , l_3 and l_4 distinctly inferior in size to preceding d and l series of setae, with the first 3 of these setae denticulate; d_3 and l_3 on the same level; d₄ situated slightly interiad from a line linking bases of d_3 and l_4 . Ventral setae ic_{2-3} long and distally fine; ic4 prominent, ending in blunt tip. Anal seta ae and genital seta g7 strong and needleshaped; g₅ vestigial. Spermatheca bell-shaped. Legs and gnathosoma as in male. Although drawings are not given, the outline of idiosoma and gnathosoma and the chaetotaxy on idiosoma and legs are similar to those depicted in Fain (1978: 218, figs. 62-63) [5] for the nominal subspecies.

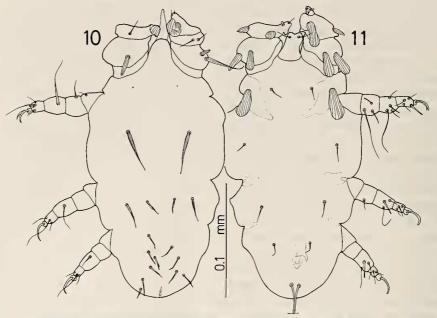

Measurements for allotype and one paratype: body 335–340 long, 160–150 wide; vi 11–12 long; ve 10–9 wide, 68–65 long; sc i 6–7 wide, 75–70 long; sc e 7–8 wide, 85–80 long; l_1 7–8 wide, 83–82 long; d_{1-2} and l_2 striated and tapering, 36–38, 31–30 and 26–28 long, respectively; ic_4 20–19 long; cx IV 14–15 long; gnathosoma 35–35 long dorsally, with 22–20 maximum width; spermatheca about 20 \times 10.

Protonymph (Figs. 10-11). Body 223 long by 118 wide. Only a single pair of well-developed

propodosomal setae and probably 7 pairs of hysterosomal setae present on idiosomal dorsum (Fig. 10); l_5 close to each other on venter; coxal setation l (shell-like)-0-0-0; intercoxal setae ic_{1-4} prominent. Anal shield lacking, but small pore visible caudally (Fig. 10). Legs I asymmetric; unideficient of dorsal seta unilaterally on femur and genu I (Fig. 10). Chaetotaxy on legs II-IV: trochanters 1-0-0; femuro-genua 4-1-0; tibiae 5-4-4; tarsi 6-6-6. Spermatheca and, partially, bursa copulatrix discernible; spermatheca bell-shaped, 18×10 .

Material examined: Holotype male, allotype female, 1 paratype male, 1 male and 1 protonymph ex Emballonura alecto (Chiroptera: Emballonuridae), PHILIPPINES: Leyte Prov., Leyte Is., 4 km S, 1 km E Inopacan, 10°28'N, 124°45'E, elev. 50 m, 5 March 1987, collector E. A. Rickart (EAR 1309), host in NMNH (catalogue #459310) (F), mite collection number HK 87-0305-3. 1 paratype female from same host species, PHILIPPINES: Leyte Prov., Maripipi Is., 3 km N, 5 km W Maripipi, elev. 50 m, 11°48'N, 124°18'E, 17 April 1987, collector P. D. Heideman (PDH 3331), host in NMNH (#459326) (F), HK 87-0417-8. Mites were recovered from the chin and body venter of the hosts. Holotype and paratypes are deposited in the collection of the UMMZ, paratypes in KU.

Remarks. Fain [6] described Ugandobia balionycteris from the holotype female and paratype nymphs found on Balionycteris maculata from Selangor, Malaysia. Then, he [7] proposed a second subspecies, Ugandobia balionycteris salomonensis, for females taken from Emballonura dianae from the Solomon Islands. Until now, the U. balionycteris subsepecies have been known only from the female and nymphs. Examination of the holotypes of both nominal subspecies (BMNH 1975.7.18.25 and 1980.5.20.246) reveals that the 2 subspecies are not as close to each other as the strong resemblance of their idiosomal chaetotaxy indicates. The most remarkable difference between them is found in the structure of the gnathosoma, which is distinctly longer than wide and almost parallel-sided with weakly concave lateral margins in the nominate subspecies and stubby with convex lateral margins in U. b. salomonensis. This structural difference seems unlikely to be of a subspecific ranking. Comparison of both subspe-

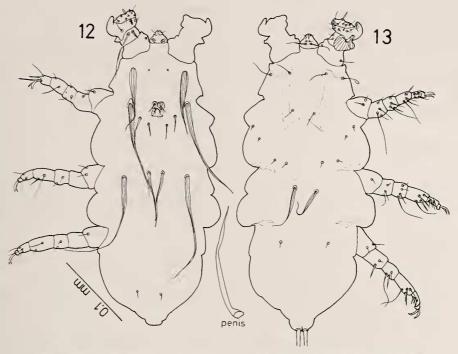

Figs. 10-11. Ugandobia balionycteris leyteensis ssp. n., protonymph. 10: Dorsal view. 11: Ventral view.

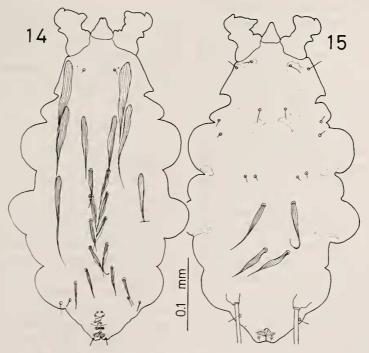

cies on the basis of adults of both sexes and immature stages will be, however, necessary to resolve the specific status of these taxa. Under these circumstances, it is difficult to allocate the present mite which shares many characters with U. balionycteris sspp. to a valid new species, so we relegate it to subspecific status. Ugandobia balionycteris leyteensis ssp. n. is unique in having l_3 situated at the level of the base of d_3 in the female. This seta is located on a level distinctly anterior to the basal level of d_3 in U. b. balionycteris and U. b. salomonensis. The gnathosoma of the present new subspecies is almost the same as in the nominate subspecies, but the body is shorter, seta vi is longer, seta l_1 is thicker, and seta cx_4 is longer in the former than in the latter. Dorsal seta d_4 is situated slightly interiad from a line linking the bases of d_3 and l_4 in the new subspecies, while it is located distinctly exterior to the line in the nominate subspecies. Among the males of 3 Ugandobia species including U. b. leyteensis, which show the coxal chaetotaxy 2-2-0-1, the male of U. emballonurae Fain is unique in having thick ve and d_2 , while the males of U. b. leyteensis and U. ituriensis Fain, 1972, share many characters with each other. The males of the latter two taxa are separable from

each other by the difference in size of setae vi, ic_2 and ic_3 . These setae are much shorter in U. b. leyteensis than in U. ituriensis.

Only a single protonymph was available in the present study. However, this specimen shows that female genital organs are formed in the earliest nymphal stage. As was the case for the spermatheca observed in the tritonymph of *U. saccolaimis*, this protonymphal spermatheca is almost as large as that in the adult female. It will be necessary to study whether the spermatheca and other copulatory organs found in immature Ugandobia mites are functional or not. The anal shield is usually observed dorsally on the hysterosoma of immature stages of mites of the family Myobiidae. However, the anal shiled is lacking on the specimens that bore copulatory organs. The chaetotaxy of the idiosoma and legs observed on the present protonymph is rather aberrant. The propodosomal setae consisting of only a single pair are not consistent with the protonymphal stage in Myobiidae, but are more typical of the larval stage as observed in U. saccolaimis and U. dissimilis [4]. Since the arrangement of the hysterosomal setae and bilaterally asymmetric setation on femur and genu I are irregular on the present protonymphal

Figs. 12-13. Metabinuncus obscuris sp. n., male. 12: Dorsal view. 13: Ventral view.

Figs. 14-15. Metabinuncus obscuris sp. n., female. 14: Dorsum. 15: Venter.

specimen (Fig. 10), the unusual propodosomal setation might also represent an abnormality, requiring futher study. A seta on trochanter II is thought to be a specific character of the protonymph of *U. balionycteris leyteensis*. Trochanter II usually lacks seta in myobiid mites in the protonymphal stage.

Metabinuncus obscuris sp. n. (Figs. 12-15)

Male (Figs. 12-13). Body 370 long by 175 wide. Dorsal seta vi minute; ve 13 wide, 65 long; sc i tapering, situated intero-posteriad from base of sc e, about 25 long; sc e 10 wide, 113 long; l₁ 7 wide, about 150 long; d_1 tapering, situated interoposteriad from base of sc i, 20 long; d_2 slightly emerging from basal level of l_1 , 10 long; d_5 9 long. Genital shield almost on basal level of sc e, bearing 6 pairs of genital setae with only the anteriormost pair being prominent. Penis thick and about 160 long. Ventral seta ic₃ thick, striated and 63 long; ic₁ and cx I slender, 13-18 long; other setae minute; coxal setae 2-3-0-0. Leg I as in Figures 12 and 13. Chaetotaxy on legs II-IV: trochanters 3-3-3; femora 5-3-3; genua 7-6-6; tibiae 6-6-6; tarsi 6-6-6. Gnathosoma small, roughly triangular.

Female (Figs. 14-15). Allotype and one paratype measured. Body 440-445 long by 250-230 wide. Dorsal seta vi 7-7 long; ve 18-18 wide, 100-98 long; sc i 10-10 wide, 80-80 long; sc e 10-13 wide, 115-113 long; l₁ 9-10 wide, about 130-120 long; d_1 , d_2 , l_2 and d_3 all of similar form, inflated in middle and then tapering; d_1 on a level anterior to bases of l_1 , 60–62 long; d_1 - d_1 (distance between d_1) 25–25; d_2 60–59 long; d_2 - d_2 23–20; l_2 54–55 long; l_2 - l_2 23–23; d_3 47–50 long; d_3 - d_3 23–23; d_4 slender, $41-40 \log; d_4-d_4 35-35; d_5 46-47 \log; d_5-d_5 63-$ 60; l_{4-5} minute. Genital lobe weakly developed; ae longer than g_7 ; g_{5-6} ending in notched tips. Ventral seate ic_3 7–7 wide, 83–93 long; ic_4 inflated, 10-10 wide and about 65-65 long; other setae as in male; g_1 (15–17 long) and g_3 (10–10 long) present. Legs and gnathosoma as in male.

Material examined: Holotype male, allotype female, 1 paratype female, 1 tritonymph and 1 protonymph *ex Hipposideros obscurus* (Chiroptera: Hipposideridae), PHILIPPINES: Negros

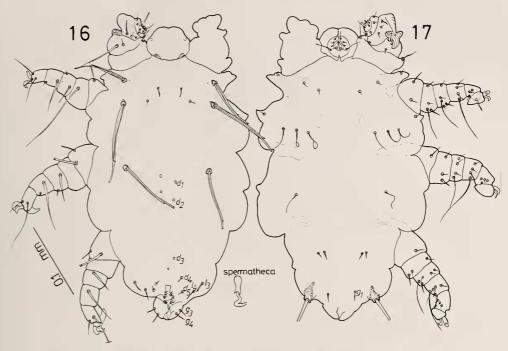

Oriental Prov., 3 km N, 14 km W Dumaguete, Lake Balinsasayao, 9°21′N, 123°11′E, elev. 850 m, 4 June 1987, collector E. A. Rickart (EAR 1642), host in NMNH (catalogue #459435) (F), mite collection number HK 87-0605-1. 2 females, 2 deutonymphs from same host species, PHILIP-PINES: Leyte Prov., Maripipi Is., 2 km N, 3 km W Maripipi, elev. 740 m, 11°47′N, 124°18′E, 17 Aprial 1987, collector P. D. Heideman (PDH 3326), host in NMNH (#459432)(F), HK 87-0417-7; 1 tritonymph, 1 deutonymph, 2 protonymphs from same host and locality, 19 April 1987, collector P. D. Heideman (PDH 3372), host in NMNH (#459433)(F), HK 87-0419-7. Mites were located on the head of the hosts.

Holotype male, allotype female and nymphs deposited in the collection of the UMMZ, other specimens in KU.

Remarks. Of the 11 known species of the genus *Metabinuncus* Fain, the males of 9 species have been described and the other two species are so far known only from the female. Only the male of *Metabinuncus hipposideros* Fain bears the genital shield on the basal level of sc e as in M. obscuris sp. n. However, the setae sc i, d_2 are much more slender in the new species than in M. hipposideros. The female of the new species is separable from those of the known species by the combination of the following characters: the inflated setae d_1 , d_2 , d_2 and d_3 , small distances between d_1 , d_2 , d_2 and d_3 , respectively, and the inflated seta ic_4 .

Pteracarus kerivoulis sp. n. (Figs. 16–17)

Female (Figs. 16–17). Body 360 long by 210 wide. Dorsal seta vi denticulate, 14 long; ve about 72 long; sc i almost on basal level of sc e, minute (9 long); sc e 98 long; l_1 78 long; d_1 , d_2 and d_3 vestigial, only basal circles discernible; d_4 and d_5 5 and 8 long, respectively; l_3 16 long; l_4 15 long. Ventral seta ic_1 minute; ic_2 and cx II slender and moderately long; ic_3 similar in form to ic_2 ; ic_4 about 10 long; g_1 15 long; g_2 lacking. Leg I as in Figures 16 and 17; anterodorsal seta of trochanter I not so strong. Chaetotaxy on legs II-IV: trochanters 3-3-3; femora 5-3-3; genua 7-6-6; tibiae 6-6-6; tarsi 6-6-6. Gnathosoma broadly rounded anter-

Figs. 16-17. Pteracarus kerivoulis sp. n., female. 16: Dorsal view. 17: Ventral view.

iorly.

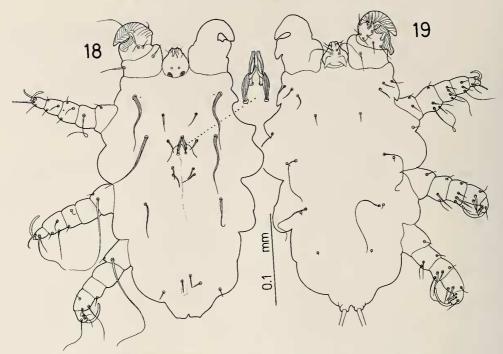

Material examined. Holotype female ex Kerivoula hardwickii (Chiroptera: Vespertilionidae), PHILIPPINES: Leyte Prov., Leyte Is., 11 km N, 5 km E Baybay, 10°47′N, 124°50′E, elev. 950 m, 19 Mrach 1987, collector P. D. Heideman (PDH 3175), host in NMNH (catalogue #459513) (F), mite collection number HK 87-0319-4. Site on the host was not recorded. The holotype is deposited in UMMZ.

Remarks. Pteracarus kervoulis sp. n., described from only the holotype female, is the 31st species of the genus Pteracarus Jameon and Chow. The new species bears the dorsal seta on genu IV and the complete d series of dorsal setae (d_{1-5}) , although d_{1-3} are vestigial. These characters place the new species as the 7th species of a group with the dorsal setae on genu IV and d_{1-5} on the idiosomal dorsum [8]. The setae d_{1-3} are visible in many species [5, 8, 9] while these setae are too short to observe only in P. macfarlanei Fain and the new species. These 2 species are differentiated by the following characters: setae vi, sc e, l_1 , ai, ae and dorsal setae on some segments of legs II-IV.

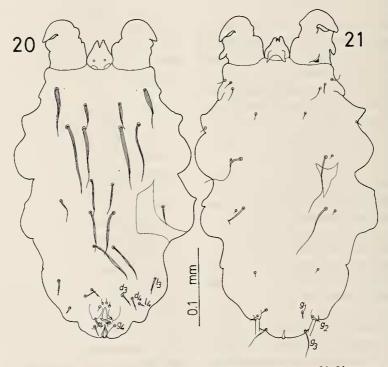

The seta vi is longer, sc e and l_1 are shorter, and the dorsal seate on leg segments are much shorter in the new species than in P. macfarlanei. The anal setae ai and ae are setiform in P. kerivoulis, but they are clavate in P. macfarlanei.

Myobia apomyos sp. n. (Figs. 18–21)

Male (Figs. 18-19). Measurements for the holotype and one paratype are given. Body 295-345 long by 180-200 wide. Dorsal seta vi thin, 15-15 long; ve 5-7 wide, 63-about 50 long; sc i on a level slightly posterior to bases of sc e, 13-15 long; sc e rather slender, about 72-72 long; l_1 about 35-about 25 long; d_1 and d_2 weakly denticulate, 15-18 long; 5 setae and 3 pairs of setae caudally on holotype and paratype, respectively. orifice slightly interoposteriad from bases of sc i; genital setae flattened and partially striated (Fig. 18). Penis 155-about 150 long. Ventral setae ic2 and ic_3 slender ad long; ic_1 about 13 long; ic_4 barely discernible; coxal setation 3-2-1-0. Leg I as in Figures 18 and 19. Chaetotaxy on legs II-IV:

Figs. 18-19. Myobia apomyos sp. n., male. 18: Dorsal view. 19: Ventral view.

Figs. 20-21. Myobia apomyos sp. n., female. 20: Dorsum. 21: Venter.

trochanters 3-3-3; femora 5-3-3; genua 7-6-5; tibiae 6-6-6; tarsi 6-6-6. Gnathosoma with prominent triangular processes ventrally.

Female (Figs. 20–21). Measurements for allotype and, in parentheses, for 2 paratypes are given. Body 380 (340–350) long by 225 (205–210) wide. Dorsal seta vi 4 (4–5) wide, 35 (32–40) long; ve 8 (7–8) wide, about 57 (58–63) long; sc i 5 (4–5) wide, 80 (73–80) long; sc e 3 (3–3) wide, 68 (58–73) long; l_1 27 (24–25) long; d_1 , d_2 and l_2 similar in form to one another, weakly inflated and ending abruptly, 33 (33–38), 47 (48–53) and 53 (48–58) long, respectively; d_3 , d_4 and l_3 weakly denticulate and ending in notched tips, about 17–18 long; l_4 8 (8–10) long. Anal setae ai, ae minute; g_7 strong; g_4 prominent; g_3 about 50 long. Ventral setae, legs and gnathosoma as in male.

Material examined: Holotype male, allotype female, 1 paratype male, 2 paratype females, 3 tritonymphs ex Apomys littoralis (Rodentia: Muridae), PHILIPPINES: Leyte Prov., Leyte Is., 11 km N, 4 km E Baybay, 10°47′N, 124°50′E, elev. 700 m, 18 March 1987, collector P. D. Heideman (PDH 3165), host in NMNH (catalogue #458755) (S), mite collection number HK 87-0318-1; 1 paratype female, 4 protonymphs, from same host species, PHILIPPINES: Leyte Prov., Leyte Is., 9 km N, 3 km E Baybay, 10°46′N, 124°49′E, elev. 500 m, collector J. S. H. Klompen (JSHK 68), host in NMNH (#459854) (F), HK 87-0402-4. All mites were collected from the head of the hosts.

Holotype and allotype in UMMZ, paratypes in NMNH, VISCA, KU.

Remarks. The known species of the genus Myobia von Heyden are divided into 2 groups according to the coxal setation, 3-2-1-1 and 3-2-1-0. Myobia musculi (Schrank), M. otomyia Lawrence, and M. apomyos sp. n. form a group with the coxal setation 3-2-1-0. Within this group, M. apomyos is characterized by weakly denticulate sc i., sc e and short l_1 in both sexes, inflated d_1 , d_2 and l_2 of the female and flattened genital setae of the male. Seven nymphs taken together with the

adults are probably 3 tritonymphs and 4 protonymphs. Although more specimens of all immature stages are necessary to describe each stage exactly, the available specimens suggest that the idiosomal chaetotaxy of the immature stages of the new species is quite different from that reported for the 4 other species of the genus *Myobia* [10].

ACKNOWLEDGMENTS

We are grateful to Dr. Anne Baker of the Arachnida and Myriapoda Section, Department of Zoology, British Museum (Natural History), London, for loan of the types of *Ugandobia balionycteris* sspp. Field work in the Philippines was supported by a grant from the U.S. National Science Foundation (BSR 8514223) to Dr. L. R. Heaney.
